B. Meningococcal Meningitis

Meningitis is inflammation of the protective membranes surrounding the brain or spinal cord, and is usually caused from an infection. Meningitis is most often caused by bacteria or a virus. Bacterial meningitis can be extremely dangerous. Symptoms can come on suddenly and progress quickly. 10-15% of cases result in death. 1 in 5 people that survive will then live with permanent disabilities such as brain damage, hearing loss, kidney damage, or limb amputation. College students are at a higher risk of contracting meningitis because of the close living quarters. Meningitis is spread by oral and nasal respiratory secretions during close contact like kissing or coughing on someone. Meningitis bacteria cannot live outside of the body for very long so is not spread as easily as a cold virus. To prevent contracting Meningitis you should receive the recommended vaccines, wash your hands, and cover your cough.
